-MEPCO

#### Acknowledgement

The following officers/officials of MEPCO developed this Medium Term Energy and Demand Forecast report.

- Mr.Hassan Raza(Assistant Manager,MEPCO) Email:hraza.mepco@gmail.com
- Mr.Asham Ahmed(Assistant Manager,MEPCO)
   Email:am.mepco@gmail.com
- Mr.Zeshan Khan Babar (Addl. Assistant Manager, MEPCO) Email:zeeshankhan@gmail.com
- Mr. Abdul Rehman (Line Superintendent-I,MEPCO) Email:faizanrahman98@gmail.com

On the eve of publishing of this report we would like to express our sincere gratitude to CPPA-G Load Forecast Consultants, Engr. Bilal Ahmed and Engr. Farhan Hussan Javed, and NTDC Load Forecast Team comprising Engr. Tauseef ur Rehman Khan – Deputy Manager Load Forecast and Mr. Shahid Abbas – Staff Economist. Their contribution and expertise have been very instrumental and invaluable for the quality of this report. Their devotion and dedication to keep the forecast methodology at par with the best international industrial practices is highly commendable. We highly appreciate the efforts of Power System Planning, NTDC for initiating the forecast process every year and facilitating all DSICOs to ensure the timely completion of the report.

PMS Team MEPCO

#### **Executive Summary**

Multan Electric Power Company (MEPCO) is currently supplying electricityto civil divisions of Bahawalpur, DG Khan, Multan, Sahiwal and their respective districts.Earlier it was known as Multan Area Electricity Board (AEB) and its distribution network in the year 2001 comprised of seventy-one 132 kV and thirty-four 66 kV sub-stations. Presently, MEPCO operates One Hundred & Seven(107)132kV and fourteen (14)66kV sub-stations.

This forecast is developed by conducting Power Market Survey (PMS), where the bottom up approach is applied considering the best international practices for the development of ten years forecast which is called Medium-term Load Forecast with facilitation from National Transmission and Despatch Company (NTDC) and Central Power Purchasing Agency Guarantee Limited (CPPA-G). The year 2017-18 has been taken as the base year and the forecast horizon is ten years up to 2027-28. The base year sale data (consumer-category wise energy sale of each feeder) and the expected spot loads data at the locations of different sub-stations have been collected by FESCO Power Market Survey team besides Transmission & Distribution losses along with the loss reduction plans, historical category-wise sale and number of consumers. Data for the base year has also been adjusted for the estimated amount of un-served energy (load shedding) in order to have realistic figures of energy consumption. Furthermore, this report is updated on yearly basis, in order to capture any potential drastic change in consumer consumption pattern.

In the year 2017-18, peak demand of MEPCO was 3,436 MW, energy sale was 15,853 GWh and energy purchased was 19,006GWh. In the total energy sale for the year 2017-18 the shares of domestic sector and industrial sector were 58% and 19% respectively. The total number of consumers in 2017-18 was 6.04 million, and number of consumers in various categories was5.37 million in domestic, 0.536 million in commercial, 0.054 million in industrial sector and 0.080 million in agricultural sector.

Forecast results show that in the years 2022-23 and 2027-28 energy sale will be 23,467GWh and 28,861GWh, peak demand will be5,255MW and 6,485MW, and energy purchased will be 27,997GWh and 34,287GWh respectively. For the period 2017-18 to 2027-28, annual average compound growth rate of energy sale, peak demand and energy purchased will be 4.88%, 4.90% and 4.78% respectively.

#### Introduction

This report is the 27<sup>th</sup>issue of Power Market Survey forecast and is prepared by MEPCOby getting assistance of CPPA-G. This forecast was previously published by Planning Power NTDCL and the current report is the second issue which is prepared by MEPCO by getting assistance from CPPA. The report consists of year wise detailed forecast of energy sale and power demand for the whole company and each sub-station within the company's distribution network. In addition, forecast for Civil Administrative areassuch asDivisions and Districts served bythe company's distribution networkisalso computed and depicted in different tables. The forecasted peak demand of MEPCO has been graphically presented in

#### Figure 1-1.

Load forecasting is an important element of the power planning process involving prediction of energy and demand in the future. The forecast serves as the basis for demand and supply-side planning. Load forecasts are typically prepared by utilities for different time frames and the level of details required depends upon different planning applications and operations for which the forecast will be used.

Long term planning requires a system level forecast of total generation requirement and peak demand. On the other hand, transmission and distribution planning requires more load level and geographic details to assess location, timing and loading of individual lines, substations and transformation facilities. The following figure(

Figure 1-1) shows the computed peak demand of MEPCO for the current forecast period.

 $\partial \partial \partial z_i^{(n)} \partial \bar z_i^{(n)}$ 

Figure 1-1: Computed Peak Demand Forecast

Forecasting models fall into the following three general categories:

- Trend models
- Econometric based models
- End-use models

Trend forecasts graphically or mathematically extrapolate past electricity demand trends into the future. They may be inadequate for short time periods where demographic changes in the underlying casual factors of load growth are not anticipated. Econometric models represent a more complex 'top-down' approach to forecasting and these models rely on the observed or the implied relationship between past energy consumption and other variables defining past economic output (likewise GDP data), demographics and price or income variables. End-use models relate energy use to the physical appliances stock levels and use patterns or industrial process. These end use models represent a 'bottom-up' forecasting approach and normally incorporate disaggregate end use forecast and consumer survey techniques.

This report has been prepared on the basis of Power Market Survey Methodology and the model used is called Power Market Survey (PMS) model. It uses bottom up approach. This model is a form of end use model which provides energy and power projections for all distribution companies and all grid stations within acompany's distribution network.

The PMS model relies on an extensive data base of historical sales. The data base includes historical figures of consumption by consumer type (i.e. domestic, industrial and commercial etc.) of each feeder of a grid station and overall consumption from a grid station. Actual consumption data isadjusted for un-served demands attributed to load shedding.

Energy forecasts are computed for each consumption category at the sub area level (grid or feeder level) on the basis of a trend analysis of recent per consumer sales plus new consumer connection applications. Industrial forecasts are based on interviews with existing consumers, trend projections and a review of the applications for request of new and increased service. These analyses are repeated for each sub area for each of the years to be forecasted. The annual peak demand is determined from the resulting energy forecasts by using the load factors and diversity factors developed for each consumer category. Forecasts are then aggregated to system level.

light and share the second of the

Because the PMS forecast is based on a mix of end-use, trend projection and known consumer expansion plans, it cannot be used reliably to predict demand over the longer term. This model had not been created to predict impacts of changes in growth of different economic sectors or consumers categories over time, or changes in both the absolute and relative prices of electricity, and of changes in the relationships between income growth and electricity growth over time as a result of market saturation and technological change (in order to capture these changes CPPA-Gis using another model called regression model). Regression model is used for long term forecasting as the changes in growth are occurred due to change in technology, life style over a longer time period.

The Power Market Survey forecast model most closely approaches the requirements of power system planning. It provides the level of detail required for siting studies and transmission and substation planning as well as the sectoral details necessary to assess different sectors growth rates and their impacts on load shapes for the system, DISCOs and grid stations. In addition, it also provides a reasonable approximation of unconstrained load growth because it makes specific provision for load shedding i.e. suppressed demand.

#### Historical Supply and Demand Analysis

#### 2.1 Category-wise Sale

The costumers within the company can be segregated in different categories. The segregation is usually based upon the type of applications for which electricity is being used. Major categories include Domestic, Commercial, Small industries, Medium & Large industries and Agriculture.

The category-wise sale (GWh) along with percentage for the years 2007-08, 2012-13, and 2017-18 are given in Figure 1-2.

#### Figure 1-2: Historical Category-wise Sale

Table 2.1-1: Historical Sale of MEPCO

#### 2.2 Transmission and Distribution Losses

In MEPCO'ssystem, losses are divided into two types;

- Transmission Losses
- Distribution Losses

The losses of 132 kV transmission lines are considered as Transmission Losses whereas the losses of 11 kV and 440 Volts lines supplying the consumers are called Distribution Losses. In a system, generally the high losses are due to lack of proper maintenance and element of theft. Reduction in losses can be achieved through installation of properly sized conductors in 11kV feeders andlow-tension lines. Installation of capacitor banks to reduce reactive power and thereby improving power factor is also and effective method to reduce line losses. The breakup of energy sent out is shown as Sale, Distribution Losses and Transmission Losses with their percentages in the Figure 1-3 for the year 2007-08,2012-13 and 2017-18.

#### 2.3 Recorded and Computed Peak Demand

¥-

Recorded peak demand is the highest electricity demand or maximum power supplied to the consumers during the base year. Computed peak demand is calculated from the recorded peak demand by adding the element of unserved power to the values of recorded peak demand. **Figure 1-4** shows the recorded and computed peak demands (MW) from the year 2013-14 to 2016-17.

Figure 1-4: Historical Recorded and Computed Peak Demands

Historical figures of recorded and computed peak, energy sale and purchase, losses and load factors for MEPCO are given in the following table.

#### 2.4 Number of Consumers

Historical figures of number of consumers within MEPCO's jurisdiction for the last five years are given in Figure 1-5. These figures show the total number of consumers in all consumer categories; i.e. Domestic, Commercial, Small industries, Medium & Large industries, Public Lighting, Bulk and Agriculture. Figure 1-5 shows a regular increase in the number of customers each year.

Figure 1-5: Number of Consumers

Category-wise number of consumers for the last five years i.e. 2013-14 to 2017-18 is shown in the following table.

| Year                       | Domestic | Commercial | Public<br>Light | Small<br>Industries | M&L<br>Industries | Tube Well | Bulk | Total   |

 Table 2.4-1: Historical Number of Consumers in MEPCO

#### Power Market Survey Methodology

#### 3.1 Overview

The Power Market Survey Model forms the basis of the Medium Term Forecast. It produces energy and peak demand forecastfor each consumer category and grid station for the entire service area over a period of ten years. The model has three inter-related components: the main database, the basic input parameters and the calculations.

A huge energy consumption database has been developed through the Power Market Survey. The database contains base year consumption data for existing consumers and ten years' forecast data for new consumers for each consumer category within the company. In addition, there is separate information for peak demand in medium & large industries and traction categories. Because of its huge volume, this data is not listed as part of the report.

In addition to the database, a number of basic input parametersare separately prepared for each DISCO which forms an integral part of the forecast model. These include:

- Growth Rates: The annual increase in consumption per consumer by consumer category
- Loss Rates: Transmission and Distribution Losses expressed as a percentage of energy purchased and energy sold, respectively
- Load Factors: It expresses the ratio of the amount of energy actually generated to the amount that would have been generated, had the peak demand been continued over the entire period.
- Coincidence Factors: Describing the load diversity within the system.

The forecast calculations within the model combine the energy consumption data and the input parameters to compute the energy and peak demand requirements within each area for each year to be forecasted. The basic data unit is an area. The data is accumulated from the area basis to grid stations, then to DISCOs and ultimately combined to produce a forecast for the entire system.

A detailed discussion of eachof the three model components is given below.

#### 3.2 Survey Base Data

An extensive database has been developed on gross consumption by consumer category such as household (domestic), commercial, small industrial, large industrial, tube wells (agriculture), public lighting, and traction (electric rail). Energy consumption figures come from consumer service meter readings. Maximum demand readings and load factors for large industrial consumers and other demand-meteredconsumers are based on service meter readings. The consumption data is collected from Computer Centers of each DISCO (It is category-wise consumption data of each feeder). The database also contains data regarding un-served demands attributed to load shedding.

The basic geographic unit represented within the database is called an area, although many areas are divided into two or more subareas. This occurs when portions of the area are served by different feeders or where a single feeder services different administrative districts. Each area is assigned a series of codes which identify the technical boundaries associated with the area.

The technical boundaries, which are emphasized in this report, start at the grid station. Thus, all areas and subareas are assigned to one of the sub-stations in each DISCO. These are distribution grid stations supplying power at 11 kV after transformation from a 132kV or 66 kV source. Grid stations are combined to form a DISCO.

a 1968

÷.

There can be up to eleven records in the data base for each area or subarea, one record for each year of forecast. The first year is typically year zero and records the base year level of consumption for each consumer category. The remaining records for the area list the incremental consumption associated with new consumers to be added to the area within the specified year.

This incremental consumption is based on applications for new or extended service which are filed at each revenue office and from discussions with the relevant industries and government agencies. Incremental industrial consumption is based on a combination of interviews, trend projections, and reviews of applications for new and/or increased service. Interviews are held with major industrial consumers to identify their current capacity utilization and any long-term plans they have for future expansion or changes in their electricity consumption. In addition, the various branches of the Ministry of Industries are interviewed to determine the number of applications received for new developments or plant expansions and the anticipated electrical load associated with each development or expansion. These anticipated new demands are added to the basic forecast of industrial consumption.

Extension of electricity to new areas over the forecast period is dealt with separately. The number of new communities to be electrified is also obtained. Initial loads and load growths are calculated based on past experience in terms of market penetration and consumption per consumer in newly electrified communities. This analysis is conducted at DISCO level. It includes new Housing schemes and new villages.

There are over 10,000 area/subarea/year records in the data base.

#### **3.3** Input Parameters

A number of input parameters are defined in order to use these in the Power Market Survey model. These parameters are:

- Transmission and Distribution Loss Rates
- The Growth Rates in consumption per consumer for each category
- Load Factors for each consumer category
- Coincidence or Diversity Factors
- Load Shedding or Unserved Energy

The definition and basic derivation of each parameter is discussed below.

t i Gelerichte beiden der State

#### 3.3.1 Growth Rates

The forecast calculations, as will be discussed below, use per consumer growth rates to update the previous year's consumption before adding the incremental consumption estimate for the current year. The Power Market Survey model requires per consumer growth rates to be specified by DISCO for each consumer category (domestic, commercial, etc.). The rates selected for the forecast

ALT STATE AND A MARKEN

are based on average annual compound growth rates, calculated from the last five years data of each consumer category in each DISCO.

#### 3.3.2 Losses

For every 100 units of electricity purchased from a power station only 75 to 85 units are actually sold to the ultimate end-user. The remaining unitsare consumed by the power system itself during transmission and distribution of the sold energy. The transmission and distribution losses must be added to the sales forecast in order to determine the total generation requirement for the system. An additional source of "loss" is the consumption in auxiliaries (also called station service) used by the power plants in the process of generating electricity. Auxiliary consumption cannot be avoided and is totally dependent on the type of generation. For example, a thermal plant would have a higher auxiliary consumption than a hydro plant to account for the energy consumed by fuel and waste handling systems. Auxiliary losses are determined and incorporated in the forecast outside the model. However, presently as the power is purchased at the bus bar level so the energy consumption in auxiliary is not calculated.

The Power Market Survey model handles Distribution and Transmission losses in such a manner thatDistribution losses are expressed as a percentage of Sales and Transmission losses are expressed as a percentage of the energy purchased from the generating stations. The model is capable of handling different loss rates of each year for each DISCO. The Distribution and Transmission losses used in the Power Market Survey Model are based on the review of current loss rates and an evaluation of existing loss reduction initiatives within the Distribution Network of the DISCO. The proposed losses (Distribution losses at 11kV and Transmission losses at 132 kV) are applied DISCO-wise. Previously a separate excel sheet was used outside the model to calculate the loss rates needed for the model. Now a separate module has been incorporated in the model to adjust 132 kV and 11 kV received and sale of a DISCO. This model simulates sale, Distribution losses and Transmission losses and Transmission losses of a DISCO. It also includes the loss reduction program.

#### 3.3.3 Load Factors

Energy sale in each consumer category is converted to peak power demand through the use of a load factor. It expresses the ratio of the amount of energy actually generated to the amount that would have been generated, had the peak demand been continued over the entire period. Load factors can be calculated over any time period but the most common are daily, weekly and annual.

The load factors utilized in the Power Market Survey Model relate annual energy sent out to peak capacity for each consumer category (domestic, commercial, public lighting, small industries and private tube wells). Input load factors are not required for medium/large industry, public tube well and traction sales as consumption for these sectors is provided through the survey in both energy and power terms.

Maximum demand readings are available directly for large industrial and other demand metered consumers such as public tube wells. Load factors for non-demand metered consumers are determined on a sample basis. For example, peak demand is based on maximum demand readings from substation feeders which are identified as serving predominantly one sector.
Domestic and commercial load factors are differentiated by community size (village, town or city). Whereas a single load factor is used for small industrial, private tube wells, public lighting and traction because of the similar nature in the operation of these loads.

33 C

### 3.3.4 Coincidence Factors

The total energy demand of a number of individual consumers is determined as the simple sum of their individual energy consumption values. The total peak load, however, is calculated as the diversified sum of their individual peak load levels. The coincidence factor, as its name implies, is a general term which measures the coincidence between the peak loads of any number of individual consumers or consumer groups over a specified time period in order to compute a combined peak. Mathematically, it is the inverse of the diversity factor.

The daily coincidence factor is determined by comparing the daily load patterns of each consumer or group under consideration. In this case, the sum of the individual hourly (or 15-minute) peaks would determine the overall daily load pattern and the overall peak load. Suppose one consumer (or group) consumes energy only in the morning and a second consumer (or group) consumes energy only in the morning and a second consumer (or group) consumes energy only in the morning and a second consumers would be zero and the peak load of the combined group would be the peak of the larger consumer. Conversely, if both groups consumed all energy at the same hour, the coincidence factor would be one and the combined peak would be the sum of the two peaks. In practice, the coincidence factor is found between these two extremes.

Coincidence factors can be determined between any group and sub-group of consumers whether it is domestic versus commercial or Lahore versus Islamabad, provided that reasonable estimates of the appropriate load patterns are available. Typically, these patterns are not readily available and must be synthesized from incomplete or estimated data. In addition, all coincidence factors calculated from these load patterns are approximations of the corresponding instantaneous peak faced by the system. In fact, a common practice is to define this instantaneous peak as the bench mark and specify all coincidence factors in relation to this peak and time. The advantage of this approach is that all peak can be easily converted into their contribution to the overall system peak, the disadvantage is that the relationship between any two groups cannot be so clearly specified and will likely be incorrectly specified.

The Power Market Survey Model depends upon specified coincidence factors between consumption categories and between consumption areas in the aggregation of peak loads from consumers to the peaks at grid stations and at DISCO level and at the level of overall system peak. The coincidence factors estimated for the medium-term model have been based on the limited available System records of the peak loads at various points in their respective systems.

### 3.3.5 Load Shedding

Actual consumption data is also adjusted for un-served demands attributed to load shedding and to voluntary restraint by consumers (e.g. an industrial consumer who agrees to close his plant or switch to captive generation during peak hours). The load shedding data is collected from National Power Control Center (NPCC) of NTDC and also from the Power Dispatch Centres of each DISCO. Now a day, all the load shedding is managed by each DISCO at its 11kV level.

an native a hite

### **3.4** Forecast Calculations

The forecast calculations involve three basic steps. Firstly, an energy forecast is determined at the area (or subarea) level using per consumer growth rates and incremental consumption estimates from the data base. This is then converted to a peak demand forecast, again at the area (or subarea) level using the input load and diversity factors. Then transmission and distribution losses are added and final step is to accumulate the areas into their corresponding grid stations, and grid stations into their DISCO and finally all DISCOs to form the system.

#### **3.5 Energy Calculations**

The basic calculation unit is the area or subarea where applicable. The database provides the base year energy consumption level for each of the six consumption categories (Domestic, Commercial, Public Lighting, Small Industry, Private Tube Wells and Medium & Large Industry). The database also includes the peak demand associated with the medium and large industry category. The domestic energy forecast for year 1 (the base year is indicated as year 0) is calculated by multiplying the base year consumption by the domestic per consumer growth rate to account for growth in the intensity of use in the sector, and then incremental consumption listed in the database is added to account for new use in the sector. This process is repeated for the remaining five energy sectors (plus the medium and large industrial demand) for the entire forecast period (remaining 10 years). The total energy consumed in the subarea for each year of the forecast period is then computed.

#### **3.6** Peak Demand Calculations

The annual energy sale values for each of the consumer category(domestic, commercial, public lighting, small industry and private tube well) are converted to peak demand using the load factors listed in the appropriate input parameter file and then adjusted to account for coincidence within the category. The annual peak demand for the subarea is computed as the sum of the individual category peaks multiplied by coincidence factors within the subarea. The sub area peak demands are accumulated to an area by applying proper coincidence factors.

#### 3.7 Accumulations

The total energy and peak demand at a given grid station is calculated as the sum of all the areas and subareas in that grid station's service area plus an allowance for distribution losses. Peak demand estimates are accumulated, and different coincidence factors applied to city, town and village areas within the service area. The total energy and peak demand within a given DISCO is the sum of all grid stations in that DISCO plus traction and an allowance for transmission losses. Peak demands are again diversified in the accumulation, and the system totals are obtained from DISCO's total with some coincidence.

## **PMS Forecast Results**

### 4.1 Recorded Forecast& Computed Forecast

The term 'Recorded Forecast' means the energy sale figures used in the forecast has not been adjusted for un-served energy (load shedding). Forecasted sale, growth rates, transmission and distribution losses, generation requirement and peak demand without incorporating load shedding has been shown in **Table 1-1**. This forecast is also called the Low Forecast.

The term 'Computed Forecast' means the energy sale figures used in forecast havebeen adjusted for un-served energy (load shedding). Forecasted energy sale, growth rates, transmission and distribution losses, generation requirement and peak demand with incorporating load shedding has been shown **Table 1-2**. Peak demand of this table has been demonstrated graphically in **Figure 1-6**. Similarly, energy sale and energy purchased also have been shown in **Figure 1-7**. The difference between energy purchased and energy sale shows all losses of the DISCO. This forecast is also called the Base Forecast. If there had not been the load shedding, the recorded forecast (Low Forecast) would have been the actual forecast i.e. the Base Forecast.

Figure 1-6: Computed Peak Demand

Figure 1-7: Energy Purchased Vs Energy Sale

### 4.2 Category-wise Forecasted Energy Sale (GWh)

Amount and percentage share of each consumer category in the total consumption for the year 2022-23 and year 2027-28 have been depicted in **Figure 1-8**. If we critically analyze **Figure 1-2** and **Figure 1-8**, it is evident that domestic sector is continuously decreasing from 49% up to 53% from year 2007-08 up to year 2027-28. Industrial sector has shown a decrease from 24% to 20% during these years which is not a healthy sign for the country's growth.

Figure 1-8: Forecasted Category Wise Sale

15

The category-wise forecasted sale incorporating load sheddingeffect (Low Forecast) is shown in **Table 1-3**. The category-wise forecasted sale with incorporating load shedding effect (Base Forecast) is shown in **Table 1-4**.

### 4.3 Category wise Forecasted Demand (MW)

The forecast of consumption (Demand) in MW without and with incorporating load shedding impact is shown in **Table 1-5** and **Table 1-6** respectively.

### 4.4 Civil Administrative Area Forecast

The MEPCO service area comprises of 4 civil administrative divisions i-e Bahawalpur, D G. Khan, Multan and Sahiwal. These divisions have 13 districts, Bahawal Nagar, Bahawal Pur, Rahimyar Khan, Lodhran, D.G. Khan, Leiah, Muzaffar Garh, Rajan Pur, Khane Wal, Multan, Vehari, Sahiwal and Pak Pattan. The civil administrative Division-wise andDistrict-wise energy and demand projections have been presented in **Table 1-7**to**Table 1-23**. The last column of the table contains peak demand.

### 4.5 Monthly Demand (MW) and Energy (GWh) Purchase Projections

The Month-wise demand (MW) and energy (GWh) purchase projections have been presented in **Table 1-24** and **Table 1-25**. To develop the projection, monthly demand and energy factors are computed for last five years and then its average is taken as a base factor for monthly demand and Energy projection. For this, each month peak is calculated from the ratio of the historical peak of that particular month to the annual historical peak of that year. Whereas each month Energy purchase is calculated from the ratio of historical monthly energy purchase of that particular month to annual energy purchase of that year. In this manner, historical ratios are calculated for each month of the last five years. The average of these values is taken as the monthly factor and multiplied with the peak demand of the year to obtain monthly peak demand and energy purchase.

#### 4.6 List of Overloaded Substations

The list of overloaded substations will inform about that particular year in which a substation will be overloaded. The overloading criterion of a substation has been considered as 100% i.e. when any substation is 100% loaded, the remedial measures should be taken in the form of new substation or augmentation of the existing transformers. **Table 1-26**&

**Table** 1-27show the lists of overloaded substations based on overloading criterion of 85% and 100% respectively. Based on the overloading criterion of 85% the number of overloaded substations in the year 2017-18 are 19. Total Ten (10) additional grids will be overloaded during years 2018-19 and 2019-20. In total, there would be 29 overloaded substations up to year 2019-20 as per 85% overloading criterion.

### 4.7 List of Grids with their Codes and MVA Capacities

The list of substations in a DISCO mentioning number of transformers with MVA capacities at each substation is provided in the

Table 1-28.

### 4.8 Peak Demand of Substations

A projection of peak demand at a substation is the most peculiar feature of this report. It is indeed a very rare and useful forecast. It provides the basis for transmission system expansion planning. It also provides a very solid ground for proposing a new substation or augmentation, extension and conversion of a sub-station. Only distribution losses have been considered in preparing the grid station peak demand forecast. The peak demand of each substation, existing as well as proposed, situated in the service area of the DISCO has been shown in **Table 1-29**.

The proposed substations during the present period have also been incorporated in this table. The demand of the proposed substations is shown on the existing grids before the commissioning of proposed substation and it is shifted to the proposed substation after its commissioning year.

#### 4.9 Peak Demands of existing, transit and proposed grids (Family of Grids)

This report also shows the projection of peak demands of existing substations as well as the demands that will be transferred to the proposed substation at when commissioned. This is also a very important forecast to accurately plan the capacity of the proposed substations as well as the status of the existing substation after the load is transferred to the proposed substation. It accurately forecast the demand in MW that will be transferred from one existing grid to the proposed grid and as well as the total load that will be transferred to the proposed grid. The peak demands of existing, transit and proposed grids are shown in

Table 1-30.Transit grid is a new term introduced in the current issue of the report. It is a virtual or temporary substation with a particular name and number on which the necessary load from one overloaded substation is shifted temporarily during base year. In

Table 1-30, the proposed grids are shown with zero loads and the transit grid shows the estimated load that will be shifted from one existing substation to the proposed grid when it is commissioned. This table helps in finding out the amount of load in the future that will be shifted to the proposed grid from the existing grid when it is commissioned.

### 4.10 Per Capita Consumption

Per capita consumption is a very vivid indicator of development in a country. Usually developed countries have very high per capita consumption. Per capita consumption (kWh/person) for the year 2012-13, 2016-17, 2017-18, 2022-23, and 2027-28 is given in **Figure 1-9**.(The consumption for the years 2021-22, and 2026-27 are obtained from forecasted data.).Population data is obtained from Pakistan census 2016-17.

Figure 1-9: Per Capita Consumption

# 4.11 Category-wise Energy and Maximum Demand Projections for each Substation

The category-wise energy and maximum demand projections for each substation have been presented in **Table 1-31**. The last two columns of the table contain power factor and reactive power values. The maximum demand for the DISCO in this table is the diversified sum of the individual peak demands of each substation and this figure will coincide with the peak demand of the respective year. In order to reduce the volume of the report, only the values of the last year i.e. 2026-27 have been presented in the table.

Table 1-1: Forecast without incorporatingLoad Sheddingeffect (Low Forecast)

#### Disclaimer

CPPA-G centrally consolidated the data from all DISCOs. The data for this report has been provided by MEPCO. So, the responsibility of accuracy of data is on MEPCO. It is also important to mention here that CPPA-G only facilitated in the preparation of this forecast as it is the prime responsibility of the DISCOs to prepare their own forecast and the DISCO prepared the same.

Further, a transition plan has been prepared by CPPA-G to help build the overall capacity of the DISCOs in-terms of people, processes and technology so that DISCOs start doing this forecast without any assistance.

• Note:

. . .

The plan is devised to transform AMI meters from top to bottom revenue bases customers.
 Price of LT / HT meters i.e. PKR 9990/- and WC meters i.e. PKR 8995/- are the lowest quouted prices taken from recent tender opened in PESCO in 09/2020
 USAID-SEP provided 2354 WC & S29 LT/HT meters during 2020-21
